1 **Abstract**

2 Invadopodia are specialized actin-based microdomains of the plasma membrane that
3 combine adhesive properties with matrix degrading activities. Proper functioning of
4 the bone, immune, and vascular systems depend on these organelles, and their
5 relevance in cancer cells is linked to tumor metastasis. The elucidation of the
6 mechanisms driving invadopodia formation is a prerequisite to understanding their
7 role and ultimately to controlling their functions. Special AT-rich sequence-binding
8 protein 2 (SATB2) was reported to suppress tumor cell migration and metastasis.
9 However, the mechanism of action of SATB2 is unknown. Here, we show that SATB2
10 inhibits invadopodia formation in HCT116 cells and that the molecular scaffold
11 palladin is inhibited by exogenous expression of SATB2. To confirm this association,
12 we elucidated the function of palladin in HCT116 using a knock down strategy.
13 Palladin knock down reduced cell migration and invasion and inhibited invadopodia
14 formation. This phenotype was confirmed by a rescue experiment. We then
15 demonstrated that palladin expression in SATB2-expressing cells restored
16 invadopodia formation. Our results showed that SATB2 action is mediated by
17 palladin inhibition and the SATB2/palladin pathway is associated with invadopodia
18 formation in colorectal cancer cells.

1 **1. Introduction**

2 Colorectal cancer (CRC) is the second leading cause of cancer deaths, with
3 approximately 500,000 deaths per year worldwide. Over the past two decades,
4 several treatments have been identified for CRC patients. However, the rate of
5 recurrence and failure after these treatments remains high. Additionally, most CRC
6 deaths are associated with tumor invasion and metastasis (1). Thus, there is a strong
7 impetus to understand the function of cancer genes involved in CRC invasiveness to
8 develop new therapeutic approaches.

9 Special AT-rich sequence-binding protein 2 (SATB2) is a member of the SATB family
10 proteins, which share structural homology consisting of CUT and homeobox domains
11 (2). SATB2 is a transcriptional factor that specifically binds to the nuclear matrix
12 attachment region (MAR) of AT-rich DNA sequences to regulate chromatin
13 remodeling and transcription (3,4). SATB2 has multiple roles in developmental
14 processes including craniofacial patterning, brain development, and osteoblast
15 differentiation (5). The chromosomal deletions of 2q33.1 that cause SATB2
16 haploinsufficiency in humans are associated with a cleft or high palate, facial
17 dysmorphism, and intellectual disability (6,7). In addition to critical roles for
18 developmental processes, previous studies have demonstrated that SATB2 is
19 associated with tumor suppression. An immunohistochemical analysis of laryngeal
20 squamous cell carcinoma (LSCC) showed that lower expression of SATB2 was
21 correlated with advanced clinical staging, histological grade and tumor recurrence (8).
22 In colorectal cancer, high expression of SATB2 is associated with good prognosis and
23 sensitivity to chemotherapy and radiation (9,10). These studies indicate that high
24 expression of SATB2 is a promising marker for the good prognosis of cancer patients;
25 however, detailed analysis of SATB2 function in cancer cells has not been fully
26 performed.

27 Palladin (PALLD) is an actin-associated protein with multiple isoforms derived from
28 a single gene (11). A recent review by L. Jin (12) described 7 isoforms and the
29 Universal Protein Database currently shows 9 isoforms of human palladin. Palladin
30 is widely expressed in various tissues and cell lines as major 90 and 140 kDa
31 isoforms, whereas 200 kDa palladin is specifically detected in heart and bone (11).
32 Palladin has an essential role in the assembly and maintenance of multiple types of
33 actin-rich structures, including stress fibers, dynamic dorsal ruffles and matrix-
34 degrading podosomes (13,14). Accumulating evidence has revealed that palladin is
35 associated with malignant characteristics of cancer. Goicoechea et al. (15) reported
36 that palladin was localized to the invadopodia of cancer cells and played important
37 roles for invasion of metastatic breast cancer cells. In pancreatic cancer, palladin is

1 expressed in cancer associated fibroblast (CAF) and an animal model demonstrated
2 that palladin expression in CAF enhanced invasion of pancreatic cancer cells (16,17).
3 In addition, a recent study showed that palladin interacts with membrane-type 1
4 matrix metalloproteinase (MMP14) to promote degradation of the extracellular
5 matrix (ECM). This interaction links ECM degradation to cytoskeletal dynamics and
6 migration signaling in mesenchymal breast cancer cells (18). These studies clearly
7 indicate that palladin plays an important role for the promotion of cancer cell
8 invasion.

9 In this study, we demonstrate that exogenous expression of SATB2 inhibits
10 invadopodia formation and invasion of colorectal cancer cells. SATB2 expression
11 suppressed expression of palladin, and restoration of palladin expression rescued
12 SATB2-mediated inhibition of invasion and invadopodia formation. This study define
13 a novel SATB2/palladin pathway for the suppression of tumor invasion.

14

15 **2. Materials and methods**

16 *Cells and antibodies*

17 HCT116, CW-2 and COLO 320 cells were obtained from ATCC and cultured in
18 DMEM (HCT116) and RPMI (CW-2 & COLO 320), supplemented with 10% FBS and
19 antibiotics. HEK293T cells used for retrovirus production were maintained in DMEM
20 with 10% FBS. The antibodies were obtained from the following companies: anti- β -
21 actin, Sigma-Aldrich (St. Louis, MO); anti-SATB2, Abcam (Cambridge, UK); anti-
22 GFP, Neuro Mab (Davis, CA); anti- α -tubulin, Sigma-Aldrich (St. Louis, MO). Anti-
23 palladin antibody was generated previously (19).

24

25 *Generation of stable cell lines*

26 Full-length SATB2 and palladin (90 kDa form) were PCR amplified from a cDNA
27 library of HCT116 cells. SATB2 was cloned into the pQCXIP vector with an N-
28 terminal GFP tag or FLAG tag and transfected into 293T cells together with the
29 pVPack-GP and pVPack-Ampho vectors using Lipofectamine 2000 (Invitrogen,
30 Carlsbad, CA). Forty-eight hours after transfection, the supernatants were added to
31 cells with 2 μ g/ml polybrene (Sigma-Aldrich). The infected cells were selected by
32 incubating with 1 μ g/ml puromycin for 2 days.

33 To establish HCT116 cell lines that constitutively expressed GFP, GFP-palladin (wt)
34 (GFP-tagged wild-type palladin) and GFP-PALLD (Res) (GFP-tagged mutant
35 palladin) each cDNA was cloned into a pQCXIN retrovirus vector (Clontech,
36 Mountain View, CA). Silent mutations were introduced in GFP-PALLD (Res) to
37 confer resistance to shRNA targeting endogenous palladin. Each plasmid was

1 transfected into HEK 293T cells together with pVPack-GP and pVPack-Ampho
2 vectors using Lipofectamine 2000 according to the manufacturer's protocol. The
3 culture supernatants were collected 48 h after transfection and applied to HCT116
4 cells in combination with 2 µg/ml polybrene (Sigma). The cells were cultured for 24 h
5 and infected cells were selected with 400 µg/ml of G418 (Nacalai Tesque, Tokyo,
6 Japan). To establish shLuc (Ctrl), shPALLD #1, shPALLD #2/GFP and shPALLD
7 #2/GFP-PALLD (Res) cells, oligonucleotides encoding shRNAs specific for human
8 palladin (#1: 5'-GTACTGGACGGCTAATGGT-3' & #2: 5'-
9 GCACAAAGGATGCTGTTAT-3') and luciferase (5'-CTTACGCTGAGTACTTCGA-3')
10 were cloned into the pSIREN-RetroQ retroviral vector (Clontech). The cells were
11 infected with recombinant retroviruses that encoded each shRNA and were selected
12 with 1 µg/ml puromycin.

13

14 *Quantitative reverse transcription–polymerase chain reaction*

15 RNA was extracted from HCT116 cells using the RNeasy Mini Kit (Qiagen, Venlo,
16 Netherlands), and cDNA was generated using PrimeScript Reverse Transcriptase
17 (TAKARA, Tokyo, Japan). PCR was performed using the SYBR Premix Ex Taq™ II
18 (TAKARA), and a Thermal Cycler Dice™ Real Time System TP800 (TAKARA) was
19 used for the analysis. The relative mRNA expression levels were normalized to
20 GAPDH. The sequences of primers used to amplify each gene were 5'-
21 AGGTGGAGGAGTGGGTGTCGCTGTT-3' and 5'-CCGGGAAACTGTGGCGTGATGG-
22 3' (GAPDH) and 5'-GCAATTCAATGCTGCTGAGA-3' and 5'-
23 GTGGCTCCTTAGTGGGTGAA-3' (palladin).

24

25 *Western blotting*

26 Cell lysates were loaded on SDS-polyacrylamide gels for electrophoresis and
27 transferred to polyvinylidene difluoride membranes (Millipore). The membranes
28 were blocked with 1% skim milk for 1 h and then incubated with primary antibodies
29 for 1 h. The membranes were then washed with TBS-T for 15 min and incubated
30 with HRP-labeled secondary antibodies. The signals were detected with the ECL
31 system (GE Healthcare BioSciences). The signal intensities were measured using
32 Light Capture II equipped with CS analyzer (ATTO Corp., Tokyo, Japan).

33

34 *Gelatin degradation*

35 Coverslips were coated with 50 µg/ml (H₂O) Poly-L(D)-Lysine (Sigma-Aldrich), fixed
36 with 0.5% glutaraldehyde (Sigma-Aldrich) and coated with 0.25 mg/ml fluorescein

1 isothiocyanate (FITC) conjugated gelatin (Elastin Products Co.). Cells were seeded on
2 the coverslips and after 22 h, the cells were fixed and immunostained.

3 4 *Wound-healing assay*

5 Wound-healing assays were performed by scratching confluent monolayers of cells
6 with a pipette tip and incubating the cells at 37°C with 5% CO₂. The distance of the
7 leading edge of the monolayer traveled was measured in five randomly selected fields
8 every 12 hours. Three independent experiments were performed, and the data are
9 shown as the mean ± SE.

10 11 *Migration assay*

12 To measure cell migration using Boyden chambers, a filter (8-μm pore size, 6.5-mm
13 membrane diameter) was pre-coated with fibronectin over night, and 2 x 10⁵ cells
14 were seeded onto the upper surface of the chamber with DMEM and 0.1% BSA
15 (serum-free). The lower chamber was filled with DMEM and 10% FBS (chemo-
16 attractant). Eighteen hours after seeding, the cells were fixed with 70% methanol
17 and stained with 0.5% crystal violet. The cells that migrated through the lower
18 surface of the filters were counted in five randomly selected fields. Three
19 independent experiments were performed, and the data are shown as the mean ± SE.

20 21 *Invasion assay*

22 To measure cell invasion using Boyden chambers, a filter (8-μm pore size, 6.5-mm
23 membrane diameter) was pre-coated with matrigel (mixture of matrix molecules
24 including laminin, collagen type IV and entactin) overnight, and 2 x 10⁵ cells were
25 seeded onto the upper surface of the chamber with DMEM and 0.1% BSA (serum-
26 free). The lower chamber was filled with DMEM and 10% FBS (chemo-attractant).
27 Twenty-four hours after seeding, the cells were fixed with 70% methanol and stained
28 with 0.5% crystal violet. The cells that invaded the lower surface of the filters were
29 counted in five randomly selected fields. Three independent experiments were
30 performed, and the data are shown as the mean ± SE.

31 32 *Immunofluorescence microscopy*

33 Cells were grown on glass coverslips, fixed with 4% paraformaldehyde for 20 min and
34 then permeabilized with 0.5% Triton X-100 for 3 min. The cells were blocked with
35 phosphate-buffered saline (PBS) containing 7% fetal bovine serum for 30 min. The
36 cells were incubated with primary antibody in PBS for 1 h and washed three times
37 with PBS. After washing, the cells were incubated with FITC-conjugated anti-rabbit

1 antibody (Invitrogen) or Rhodamine-conjugated anti-mouse antibody (Invitrogen).
2 The images were acquired using a laser scanning confocal microscope FV1000
3 (OLYMPUS, Tokyo, Japan). To visualize the actin cytoskeleton the fixed cells were
4 incubated with rhodamine-conjugated phalloidin for 30 min and washed.

5

6 *Statistical analysis*

7 The statistical analysis is indicated in each corresponding figure legend. All data are
8 the mean \pm SE from 3 independent assays. All analyses were examined using the
9 SigmaPlot program version 10.0 (Systat Software, Inc., San Jose, CA). The P- values
10 were calculated from two-tailed statistical tests. A difference was considered
11 statistically significant when $P < 0.05$.

12

13 **3. Results**

14 *3.1. SATB2 expression inhibits invadopodia formation*

15 SATB2 has been shown to have tumor suppression function and downregulation of
16 SATB2 is associated with metastasis and poor prognosis in CRC. We generated
17 HCT116 cells that constitutively expressed FLAG-SATB2 or FLAG tag and examined
18 cell invasion. **Expression of FLAG-SATB2 was significantly higher than endogenous**
19 **SATB2 (Fig. 1A).** We assessed cell invasion using a matrigel-coated Boyden Chamber.
20 As shown in Fig. 1B, invasion of FLAG-SATB2-expressing HCT116 cells was clearly
21 reduced compared to that of FLAG-expressing cells. Invadopodia are highly motile
22 membrane extensions that promote degradation of extracellular matrix for cell
23 invasion. We examined whether SATB2 expression in HCT116 cells suppressed
24 invadopodia formation. Invadopodia are usually visualized by co-staining cells with
25 cortactin and F-actin. Additionally, it is important to determine that the co-staining
26 is on the ventral surface of the cell using either confocal or TIRF microscopy. We
27 used the confocal microscopy after co-staining with phalloidin (red) and cortactin
28 (green) to detect invadopodia. As shown in Figure 1C, the invadopodia can be
29 identified by their dot-like concentrations of cortactin. The invadopodia were found
30 scattered over the ventral membrane of the FLAG-expressing cells. However, FLAG-
31 SATB2-expressing cells showed reduced dot-like concentrations of cartactin and a
32 decreased percentage of cells with invadopodia with a 1.6-fold decrease compared to
33 FLAG-expressing cells (Figure 1A). To confirm that the cortactin-positive dots are
34 functional invadopodia, we used glass coverslip coated with FITC-labeled gelatin.
35 Cells were cultured on the FITC-labeled gelatin and then degradation of gelatin was
36 observed by confocal microscopy. Degradation of FITC-labeled gelatin was observed

1 where cortactin was prominently concentrated, suggesting that cortactin-rich area
2 have ability to degrade extracellular matrix.

3 4 *3.2. Expression of SATB2 inhibits palladin*

5 Palladin was reported to promote formation of podosomes and invadopodia in normal
6 and cancer cells, respectively (20). To elucidate the molecular mechanism by which
7 SATB2 exerts its action, we examined palladin expression in SATB2-expressing cells.
8 We generated either GFP- or GFP-SATB2-expressing HCT116 cells by retrovirus
9 infection (Fig. 2A) and examined palladin mRNA level by RT-PCR. As shown in Fig.
10 2B, palladin mRNA was significantly reduced by GFP-SATB2 expression. To further
11 confirm the suppression of palladin expression by exogenous SATB2, we generated
12 CW-2 and COLO320 cells that constitutively expressed GFP-SATB2. Immunoblot
13 analysis showed that expression of multiple palladin isoforms (200, 140, 115, 90 and
14 50 kDa) was significantly decreased by GFP-SATB2 (Fig. 2C).

15 16 *3.3. Palladin depletion in HCT116 suppresses cell migration and invasion*

17 We speculated that SATB2-mediated suppression of invasion and invadopodia
18 formation were mediated by decreased palladin expression. To evaluate the function
19 of palladin, we used two different shRNAs to deplete palladin expression. Palladin
20 was highly expressed in HCT116, CW-2 and COLO320 cells, but not in DLD-1,
21 CACO-2 SW620 and COLO205 cells (Fig. 3A). We used HCT116 cells for further
22 experiment and established HCT116 cells that constitutively expressed control
23 shRNA (shCtrl) or palladin shRNA (shPALLD#1 and shPALLD#2). Expression of
24 palladin was clearly suppressed in shPALLD#1 and shPALLD#2 cells (Fig. 3B). We
25 first examined cell migration in the absence of palladin. Confluent monolayers of
26 cells were scratched and distance of the migrated leading edges was measured every
27 12 h. The migration of palladin-depleted cells was clearly delayed compared with
28 that of the shCtrl cells (Fig. 3C). To further confirm this result, we used a modified
29 Boyden chamber assay. The migration of both shPALLD#1 and shPALLD#2 cells was
30 clearly suppressed compared with that of the shCtrl cells (Fig. 3D). We next
31 examined cell invasion using matrigel-coated Boyden chambers. As shown in Fig. 3E,
32 cell invasion was significantly suppressed by palladin knockdown.

33 34 *3.4. Palladin localizes to invadopodia and enhances its formation*

35 Cancer cell invasion involves degradation of ECM via formation of invasive
36 morphological features including invadopodia. We immunostained cells for F-actin
37 and cortactin, and then observed using a confocal microscopy to evaluate invadopodia

1 formation. In shCtrl HCT116 cells, invadopodia appeared as isolated puncta located
2 behind the leading edge of the cell or under the nucleus (Figure 4A). Consistent with
3 the reduced cell invasion in the absence of palladin, invadopodia formation was
4 suppressed in both shPALLD#1 and shPALLD#2 cells. Nearly 60 % of shCtrl cells
5 had cortactin concentrated area, whereas less than 30 % of palladin-depleted cells
6 showed cortactin accumulation (Fig. 4B). These results suggest that palladin plays
7 an important role in promoting invadopodia formation in HCT116 cells. We used
8 immunostaining to visualize endogenous palladin in HCT116 cells to determine
9 whether palladin is recruited to these actin-based structures. As shown in Fig. 4C,
10 partial co-localization of palladin and cortactin was observed in HCT116 cells.
11 We next performed a rescue experiment using HCT116 cells to exclude the possibility
12 that the observed phenotype was induced by the off-target effect of the shRNAs. To
13 exogenously express palladin, we used 90 kDa isoform because the isoform is highly
14 expressed in multiple tumor tissues and is known to promote tumor cell invasion.
15 We generated HCT116 cells that constitutively expressed GFP or GFP-palladin(Res)
16 by retrovirus infection. GFP-palladin(Res) has silent mutations to be resistant to
17 shPALLD#2-mediated knockdown. Both cell lines were then infected with shPALLD
18 #2-encoding retrovirus to generate shPALLD#2/GFP and shPALLD#2/GFP-palladin
19 cells. Expression of endogenous palladin was reduced by shPALLD#2, but the
20 expression of GFP-palladin(Res) was not affected (Fig. 5A). We performed an
21 immunofluorescence analysis to observe invadopodia formation. The GFP-expressing
22 cells showed a reduced frequency of invadopodia formation by shPALLD#2
23 expression. In contrast, the introduction of shPALLD#2 did not affect invadopodia
24 formation in GFP-palladin(Res) cells (Figure 5B). These results show that
25 invadopodia formation was specifically promoted by palladin.

26

27 *3.4. SATB2 represses cell invasion and invadopodia formation via palladin inhibition*

28 We next tested if SATB2-mediated suppression of cell invasion and invadopodia
29 formation were mediated by palladin inhibition. We infected FLAG-SATB2 HCT116
30 cells with GFP or GFP-palladin (90 kDa isoform) and then assessed invadopodia
31 formation. Although expression of endogenous palladin in FLAG-SATB2/GFP-
32 palladin cells was reduced compared to that in FLAG cells, GFP-palladin was
33 expressed to the level compatible with the endogenous palladin in FLAG cells (Fig.
34 6A). **Cell invasion assay demonstrated that expression of palladin in FLAG-SATB2**
35 **cells clearly restored invasive activity similar to the level of FLAG cells (Fig. 6B).** We

1 next examined whether invadopodia formation was restored by palladin expression.
2 Cells were immunostained for cortactin and observed under the confocal microscopy.
3 As shown in Figure 6B, FLAG-SATB2/GFP cells showed GFP fluorescence
4 distributed over the cells and low dot-like concentrations of cortactin. However,
5 FLAG-SATB2/GFP-palladin cells showed an accumulation of GFP-palladin and
6 cortactin at the edge of cells (Fig. 6C). We quantified these results and found that the
7 percentage of cells with invadopodia in FLAG-SATB2/GFP-palladin cells increased
8 1.6-fold compared to FLAG-SATB2/GFP cells. Collectively, these results indicate that
9 the suppression of cell invasion and invadopodia formation by SATB2 was partly
10 mediated by inhibition of palladin.

11

12 **4. Discussion**

13 In this report, we showed that SATB2 mediated inhibition of invadopodia formation
14 and invasion was partly mediated by suppression of palladin expression. **Expression**
15 **of SATB2 in HCT116, CW-2, COLO320 clearly suppressed expression of multiple**
16 **isoforms of palladin. In addition, palladin mRNA in HCT116 was reduced by SATB2**
17 **expression. These results clearly indicate that SATB2 expression can directly or**
18 **indirectly suppress palladin expression.** SATB2 has homeodomain and CUT domain
19 that can associate with NAR or conserved DNA sequence. Analysis with deletion
20 constructs showed that CUT domain, but not homeodomain, was critical for the
21 suppression of palladin expression. This result indicates that CUT domain mediated
22 SATB2 localization to NAR is critical for the palladin inhibition. **SATB2-mediated**
23 **chromosome rearrangement may induce structural changes in the genomic region of**
24 **palladin and suppress its expression. MicroRNAs are small RNAs that bind to mRNA**
25 **to inhibit translation or promote mRNA degradation. Most of the microRNA target**
26 **regions are located to the 3'UTR of mRNAs. SATB2 expression suppressed multiple**
27 **isoforms and they have the same 3'UTR regions. Therefore, we cannot exclude the**
28 **possibility that microRNAs induced by SATB2 may have caused reduction of palladin**
29 **expression.**

30 Accumulating evidence has demonstrated that palladin plays a crucial role for cancer
31 cell migration and invasion. **Palladin can bind to multiple actin-associated proteins,**
32 **such as actinin, lasp1 and CLP36, and contribute rearrangement of actin**
33 **cytoskeleton for cell migration.** Two opposing functions of palladin for cell migration
34 have been reported. We and Chin et al previously reported that palladin inhibition
35 promoted cell migration, and phosphorylation palladin by ERK or AKT regulated
36 palladin-mediated migration suppression. In contrast, other groups clearly showed

1 that palladin depletion suppressed cell migration as well as actin cytoskeletal
2 organization. In this analysis, we examined effect of palladin knockdown on cell
3 migration using wound healing assay and transwell chamber. In both analyses, we
4 found that palladin knockdown clearly suppressed cell migration. Organization of
5 actin cytoskeleton is significantly different between cancer cell lines. For example,
6 some cancer cell lines, such as SAOS2, have thick and bundled actin stress fibers,
7 whereas many of cancer cells do not show clear formation of stress fibers. In addition,
8 critical regulators for actin cytoskeleton and cell migration, such as RhoA, Rac1 and
9 CDC42, show different activity among cancer cells. Depending on the cellular context,
10 expression of palladin may promote or suppress cell migration.

11 In this study, we used 90 kDa form of palladin for rescue experiment. Palladin has
12 multiple forms and most of them have C-terminal IgG domains. IgG domains are
13 90kDa form has three IgG domains in the C-terminus, and 140 kDa and 200 kDa
14 have additional two IgG domains in the N-terminus. Furthermore, 140kDa and
15 200kDa isoforms have two SH3 binding regions, whereas 90 kDa isoform has only
16 one region. Although a difference in function between palladin isoforms remains
17 obscure, a previous study reported that 140 kDa has specific binding partner. Lasp1,
18 which is an actin-binding protein, interact with proline rich region specific to 140 and
19 200 kDa isoforms. Overexpression of 90 kDa palladin induced bundling of stress fibers,
20 whereas 140 kDa isoform produced star-like arrays of actin fibers, indicating these
21 isoforms have different functions in actin cytoskeletal rearrangement. In this study,
22 we used 90 kDa isoform for the rescue experiment. Although HCT116 cells expressed
23 multiple isoforms of palladin and both shRNAs suppressed these isoform, expression
24 of 90 kDa palladin was sufficient to rescue invadopodia formation and invasion.
25 Although other isoforms may be associated with actin cytoskeletal rearrangement
26 and cellular functions, our results show that 90 kDa palladin is a major isoform that
27 control invadopodia formation and cell invasion.

28 In summary, we have shown that SATB2 expression suppressed invadopodia
29 formation as well as invasion by inhibiting expression of palladin. Accumulating
30 studies have shown that palladin interacts with multiple proteins and functions as a
31 scaffold for numerous signal transductions. SATB2 may modulate signal pathways
32 mediated by palladin for the various changes in cellular context for the suppression
33 of tumor progression.

9 **Figure legends**

10 **Figure 1.** SATB2 expression inhibits invadopodia formation and cancer cell invasion.

11 (A) HCT116 cells that constitutively expressed either FLAG or FLAG-SATB2 were
12 established by retrovirus infection. The cells were fixed with 4% paraformaldehyde
13 and immunostained for F-actin (phalloidin; red) and cortactin (green).
14 Representative micrographs are shown (scale bar = 20 μ m) and the graph shows the
15 average percentage of cells with invadopodia (*P<0.05). The arrows indicate the
16 invadopodia concentrations. (B) HCT116 cells were seeded on fluorescein
17 isothiocyanate (FITC)-gelatin (green), fixed with 4% paraformaldehyde and
18 immunostained for cortactin (red). Representative micrographs are shown (scale bar
19 = 20 μ m). (C) FLAG or FLAG-SATB2 HCT116 cells were subjected to an invasion
20 assay. Representative images of invaded cells are shown, and the graph indicates the
21 average number of invaded cells per field (*P<0.05).

22

23 **Figure 2.** SATB2 expression inhibits palladin expression. (A) HCT116 cells
24 constitutively expressing GFP (GFP) or GFP-tagged SATB2 (GFP-SATB2) were
25 generated by retroviral infection. The expression of GFP or GFP-SATB2 proteins in
26 each cell line was examined by immunoblotting using anti-GFP and anti-SATB2
27 antibodies. An arrow indicates the endogenous SATB2. (B) The level of palladin
28 mRNA in GFP- and GFP-SATB2 cells was determined by qRT-PCR (C) Palladin
29 expression in either GFP or GFP-SATB2 expressing cells was determined by
30 immunoblotting. The arrows indicates the 200, 140, 115, 90 and 50 kDa palladin
31 isoforms.

32

33 **Figure 3.** Palladin depletion reduces cancer cell migration and invasion. (A) Palladin
34 expression was detected in seven colorectal cancer cell lines by immunoblotting. (B)
35 HCT116 cells constitutively expressing shCtrl, shPALLD #1 and shPALLD #2 were
36 generated by retroviral infection. The palladin expression was detected in these cell

1 lines by immunoblotting. (C) Confluent monolayers of shCtrl, shPALLD #1 or
2 shPALLD #2 HCT116 cells were scratched, and cell migration was examined every 12
3 h. Representative images of migrated cells are shown, and the graph shows the
4 average migrated distance at the indicated time points (*P<0.05). (D) ShCtrl,
5 shPALLD #1 or shPALLD #2 HCT116 cells were subjected to the migration assay.
6 Representative images of migrated cells are shown, and the graph indicates the
7 average number of migrated cells per field (*P<0.05). (E) ShCtrl, shPALLD #1 or
8 shPALLD #2 HCT116 cells were subjected to an invasion assay. Representative
9 images of invaded cells are shown, and the graph indicates the average number of
10 invaded cells per field (*P<0.05).

11

12 **Figure 4.** Palladin depletion inhibits invadopodia formation. (A) HCT116 cells that
13 constitutively expressed shCtrl, shPALLD #1 or shPALLD #2 were fixed with 4%
14 paraformaldehyde and immunostained for F-actin (phalloidin; red) and cortactin
15 (green). Representative micrographs are shown (scale bar = 20 μ m) and the graph
16 shows the average percentage of cells with invadopodia (*P<0.05). The arrows
17 indicate the invadopodia concentrations. (B) HCT116 cells were fixed with 4%
18 paraformaldehyde and immunostained for cortactin (green) and palladin (red).
19 Representative micrographs are shown (scale bar = 20 μ m).

20

21 **Figure 5.** Rescue of palladin restores invadopodia formation. (A) HCT116
22 constitutively expressing shCtrl, shPALLD #2/GFP and shPALLD #2/GFP PALLD
23 (Res) were generated by retroviral infection. The endogenous and exogenous palladin
24 expression was detected in these cell lines by immunoblotting using anti-palladin
25 and anti-GFP. An arrow indicates exogenous palladin level. (B) HCT116 cells that
26 constitutively expressed shPALLD #2/GFP and shPALLD #2/GFP PALLD (Res) were
27 fixed with 4% paraformaldehyde and immunostained for GFP (green) and cortactin
28 (red). Representative micrographs are shown (scale bar = 20 μ m). The graph
29 indicates the average percentage of cells with invadopodia in the cells (*P<0.05).

30

31 **Figure 6.** Palladin expression restores invadopodia formation in SATB2-expressing
32 cells. (A) HCT116 cells constitutively expressing FLAG, FLAG-SATB2/GFP and
33 FLAG-SATB2/GFP-palladin were generated by retroviral infection. Endogenous and
34 exogenous palladin expression were detected by immunoblotting using anti-palladin
35 and confirmed by anti-GFP. An arrow indicates the exogenous palladin expression
36 (B) HCT116 cells that constitutively expressed FLAG-SATB2/GFP were fixed with
37 4% paraformaldehyde and immunostained for GFP (green) and cortactin (red).

1 Representative micrographs are shown (scale bar = 20 μ m) (C) HCT116 cells that
2 constitutively expressed FLAG-SATB2/GFP-palladin (wt) were fixed with 4%
3 paraformaldehyde and immunostained for GFP (green) and cortactin (red).
4 Representative micrographs are shown (scale bar = 20 μ m). The graph indicates the
5 average percentage of cells with invadopodia in FLAG-SATB2/GFP and FLAG-
6 SATB2/GFP-palladin cells (*P<0.05).
